# DATA STRUCTURE

## Definition

A data structure is a systematic way of collecting, organizing, and storing data so that it can be accessed and manipulated efficiently.

## Type of data structure

### Primitive Data Types

Basic building blocks used to store simple values:

- **int** – Integer numbers
- **char** – Single characters
- **float** – Floating-point numbers (decimal numbers)
- **double** – Double-precision floating-point numbers
- **boolean** – True or False values
- **string** – Sequence of characters

### Non-Primitive Data Types

More complex structures built using primitive types. They can be **linear** or **non-linear**.

#### 1. Linear Data Structures

Elements are arranged sequentially:

- **Array** – A collection of elements of the same type stored in contiguous memory
- **Linked List** – A sequence of nodes where each node points to the next
- **Stack** – Last-In-First-Out (LIFO) structure
- **Queue** – First-In-First-Out (FIFO) structure

#### 2. Non-Linear Data Structures

Elements are connected in a hierarchical or networked way:

- **Tree** – Hierarchical structure with a root node and child nodes
- **Graph** – Collection of nodes (vertices) connected by edges

# LINKED LIST

## Definition

A linked list is a linear data structure consisting of a sequence of elements called **nodes**, where each node contains data and a reference (or pointer) to the next node in the sequence.

## Linked list vs Array

### ARRAY

- **FIXED SIZE**
- Difficult to add or remove elements
- Must reserve consecutive memory locations; access to elements is fast and in constant time

### LINKED LIST

- **FLEXIBLE SIZE**
- Easy to add or remove elements
- Consecutive memory locations are not necessary; access to elements is slower and in non-constant time

## Types of Linked List

1. **Singly Linked List:**
  - Each node points only to the next node.
  - Can move only forward.
2. **Doubly Linked List:**
  - Each node contains a pointer to the next node and a pointer to the previous node.
  - Can move forward and backward.
3. **Circular Linked List:**
  - The last node points to the first node, forming a circular structure.
  - Can exist in singly or doubly linked forms.

## Singly Linked List

## Doubly Linked List

## Circular Linked List

## Basic Operations

1. **Insertion:**
  - At the beginning (Head)
  - At the end (Tail)
  - After a specific node
2. **Deletion:**
  - From the beginning
  - From the end
  - Specific element
3. **Traversal:**
  - Go through all elements to print or search for a value

# STACK

## Definition

A **Stack** is a data structure that follows the **LIFO (Last In, First Out)** principle.

The last element inserted is the first one to be removed.

## Basic Operations

1. **Push:** Insert an element into the stack.
2. **Pop:** Remove the last inserted element.
3. **Peek / Top:** Show the top element without removing it.
4. **isEmpty:** Check if the stack is empty.
